Variable Assignment

Rules for variable names

- · names can not start with a number
- · names can not contain spaces, use intead
- names can not contain any of these symbols:

```
:'",<>/?|\!@#%^&*~-+
```

- it's considered best practice (<u>PEP8 (https://www.python.org/dev/peps/pep-0008/#function-and-variable-names)</u>) that names are lowercase with underscores
- avoid using Python built-in keywords like list and str
- avoid using the single characters 1 (lowercase letter el), 0 (uppercase letter oh) and I (uppercase letter eye) as they can be confused with 1 and 0

Dynamic Typing

Python uses *dynamic typing*, meaning you can reassign variables to different data types. This makes Python very flexible in assigning data types; it differs from other languages that are *statically typed*.

```
In [1]: my_dogs = 2
In [2]: my_dogs
Out[2]: 2
In [3]: my_dogs = ['Sammy', 'Frankie']
```

```
In [4]: my_dogs
Out[4]: ['Sammy', 'Frankie']
```

Pros and Cons of Dynamic Typing

Pros of Dynamic Typing

- · very easy to work with
- · faster development time

Cons of Dynamic Typing

- · may result in unexpected bugs!
- you need to be aware of type()

Assigning Variables

Variable assignment follows name = object , where a single equals sign = is an assignment operator

```
In [5]: a = 5
In [6]: a
Out[6]: 5
```

Here we assigned the integer object 5 to the variable name a . Let's assign a to something else:

```
In [7]: a = 10
In [8]: a
Out[8]: 10
```

You can now use a in place of the number 10:

```
In [9]: a + a
Out[9]: 20
```

Reassigning Variables

Python lets you reassign variables with a reference to the same object.

```
In [10]: a = a + 10

In [11]: a

Out[11]: 20

There's actually a shortcut for this. Python lets you add, subtract, multiply and divide numbers with reassignment using += , -= , *= , and /= .

In [12]: a += 10

In [13]: a

Out[13]: 30

In [14]: a *= 2

In [15]: a

Out[15]: 60
```

Determining variable type with type()

You can check what type of object is assigned to a variable using Python's built-in type() function. Common data types include:

- int (for integer)
- float
- **str** (for string)
- list
- tuple
- dict (for dictionary)
- set
- bool (for Boolean True/False)

```
In [16]: type(a)
Out[16]: int
In [17]: a = (1,2)
In [18]: type(a)
Out[18]: tuple
```

Simple Exercise

This shows how variables make calculations more readable and easier to follow.

```
In [19]: my_income = 100
    tax_rate = 0.1
    my_taxes = my_income * tax_rate
In [20]: my_taxes
```

Out[20]: 10.0

Great! You should now understand the basics of variable assignment and reassignment in Python. Up next, we'll learn about strings!
